1 Introduction and Motivation

Generative Adversarial Networks (GANs) [GPAM⁺14] and their variants revolutionized the field of computer vision in the year of 2014, enabling advancements in multiple areas of generating data. From *Text to Image Synthesis* [RAY⁺16], *Image Translation* [IZZE18], *Super Resolution* [LTH⁺17], *Image Inpainting* [PKD⁺16], *Style Transfer* [WWR⁺23] to *Data Augmentation* [SK19], GANs have been used in a variety of applications.

The idea of using GANs for Generative Data Augmentation (GDA) has already been applied successfully, e.g.: in computer vision [JLR25], [BNI⁺23] or for creating music [JLY20]. Especially the former survey *A Comprehensive Survey of Image Generation Models Based on Deep Learning* has, along Variational Auto Encoders (VAEs), a dedicated focus on GANs. Despite of the mentioned achievements, in praxis GANs suffer from multiple problems, complicating the training and inference process:

- Mode Collapse
- Loss of inter-class Diversity
- Failure to Converge
- Vanishing Gradients
- Unstable Gradients
- Imbalance between Generator- and Discriminator Model

This thesis investigates the potential of using GANs - specifically *Multi-Agent Diverse Generative Adversarial Networks* (MADGANs) [GKN⁺18] - for Generative Data Augmentation. MADGANs aim to aid the first two of the afore mentioned in particular: Mode Collapse and Loss of inter-class Diversity. They, along other modifications, "*propose to modify the objective function of the discriminator, in which, along with finding the real and the fake samples, the discriminator also has to correctly predict the generator that generated the given fake sample.*" [GKN⁺18]. The goal of this adjustment of the discriminator is, that the discriminator has to push the generators towards distinct identifiable modes. In their paper, they experimentally show, that their architectural adjustment of GANs is generally capable of giving providing assistance for first two of the mentioned problems.
